

PLC ASSIGNMENT-3

SIDDHANT CHAUDHARY
BMC201953

1. Recall the definition of *parallel reduction*. It is the relation \Longrightarrow over λ -terms defined by the following rules.

$$\overline{M \Longrightarrow M}$$

$$\overline{(\lambda x.M)N \Longrightarrow M[x := N]}$$

$$\frac{M \Longrightarrow M'}{\lambda x.M \Longrightarrow \lambda x.M'}$$

$$\frac{M \Longrightarrow M' \quad N \Longrightarrow N'}{MN \Longrightarrow M'N'}$$

$$\frac{M \Longrightarrow M' \quad N \Longrightarrow N'}{(\lambda x.M)N \Longrightarrow M'[x := N']}$$

Define M^* as follows.

$$\begin{aligned} x^* &= x \\ (\lambda x.M)^* &= \lambda x.M^* \\ (MN)^* &= M^*N^* \quad (M \text{ not of the form } \lambda x.P) \\ ((\lambda x.P)N)^* &= P^*[x := N^*] \end{aligned}$$

Prove the following.

(a) If $M \rightarrow_\beta N$ then $M \Longrightarrow N$.

Proof. Suppose $M \rightarrow_\beta N$, i.e M β -reduces to N in a single step. So, M contains a β -redux, say $(\lambda x.P)Q$, as a sub-term, and suppose the reduction $M \rightarrow_\beta N$ is the reduction of this redux. By the second rule above, we know that

$$(\lambda x.P)Q \Longrightarrow P[x := Q]$$

and hence we conclude that $M \Longrightarrow N$. This proves the claim. ■

(b) If $M \Longrightarrow N$ then $M \xrightarrow{*}_\beta N$.

Proof. Suppose $M \Longrightarrow N$. We prove the claim by induction on the length of the λ -terms. For the base case, suppose $M \Longrightarrow N$, and the length of the term M is 1. Clearly, $M = x$, where x is a variable, and the reduction $M \Longrightarrow N$ is $x \Longrightarrow x$. In this case, it is obvious that $x \xrightarrow{*}_\beta x$, i.e $M \xrightarrow{*}_\beta N$. So the base case is true.

Date: April 30, 2021.

Next, suppose the claim is true for all λ -terms M of length at most $n - 1$ for some $n - 1 \in \mathbb{N}$. Then, suppose $M \Longrightarrow N$, and suppose the length of the λ -term M is n . We have the following cases.

- (1) In the first case, the reduction $M \Longrightarrow N$ is of the form $M \Longrightarrow M$. Clearly, in that case, we have $M \xrightarrow{*}_\beta M$ in zero steps.
- (2) In the second case, suppose the reduction $M \Longrightarrow N$ is of type two, i.e M contains a redex $(\lambda x.P)Q$, and the reduction $M \Longrightarrow N$ involves the reduction $(\lambda x.P)Q \Longrightarrow P[x := Q]$. Clearly, in this case, we have

$$(\lambda x.P)Q \xrightarrow{*}_\beta P[x := Q]$$

in one step, and hence $M \xrightarrow{*}_\beta N$ in one step.

- (3) In the third case, suppose the reduction $M \Longrightarrow N$ is of type three. So, M contains a term $\lambda x.P$ such that $P \Longrightarrow Q$, and the reduction $M \Longrightarrow N$ involves the reduction $\lambda x.P \Longrightarrow \lambda x.Q$. Clearly, the length of the term P is at most $n - 1$, and by induction hypothesis, we know that $P \xrightarrow{*}_\beta Q$. So, it follows that

$$\lambda x.P \xrightarrow{*}_\beta \lambda x.Q$$

and hence

$$M \xrightarrow{*}_\beta N$$

in this case as well.

- (4) In the next case, the reduction $M \Longrightarrow N$ is of the fourth type. So, M contains a term of the form PS such that $P \Longrightarrow P'$, $S \Longrightarrow S'$, and the reduction $M \Longrightarrow N$ involves the reduction $PS \Longrightarrow P'S'$. Again, note that the length of the terms P and S is at most $n - 1$, and by induction hypothesis, we see that

$$P \xrightarrow{*}_\beta P' \quad , \quad S \xrightarrow{*}_\beta S'$$

This means that

$$PS \xrightarrow{*}_\beta P'S \xrightarrow{*}_\beta P'S'$$

and hence it follows that

$$M \xrightarrow{*}_\beta N$$

in multiple steps.

- (5) In the next case, the reduction $M \Longrightarrow N$ is of the fifth type. So, M contains a term $(\lambda x.P)Q$, where $P \Longrightarrow P'$, $Q \Longrightarrow Q'$, and the reduction $M \Longrightarrow N$ involves the reduction $(\lambda x.P)Q \Longrightarrow P'[x := Q']$. Again, note that the lengths of P and Q is at most $n - 1$. So, by the induction hypothesis, we see that $P \xrightarrow{*}_\beta P'$ and $Q \xrightarrow{*}_\beta Q'$. So, it follows that

$$(\lambda x.P)Q \xrightarrow{*}_\beta (\lambda x.P')Q \xrightarrow{*}_\beta (\lambda x.P')Q' \xrightarrow{*}_\beta P'[x := Q']$$

So, it follows that

$$M \xrightarrow{*}_\beta N$$

in multiple steps.

So by induction, the claim is true for all terms M . This completes the proof. ■

(c) $M \xrightarrow{*}_\beta N$ if and only if $M \Longrightarrow N$.

Proof. First, suppose $M \xrightarrow{*}_{\beta} N$. So, there is a sequence M_1, \dots, M_k of λ -terms such that

$$M \rightarrow_{\beta} M_1 \rightarrow_{\beta} M_2 \rightarrow_{\beta} \cdots \rightarrow_{\beta} M_k \rightarrow_{\beta} N$$

By part **(a)**, we see that

$$M \Longrightarrow M_1 \Longrightarrow M_2 \Longrightarrow \cdots \Longrightarrow M_k \Longrightarrow N$$

and hence $M \xRightarrow{*} N$.

Conversely, suppose $M \xRightarrow{*} N$. So, there is a sequence M_1, \dots, M_k of λ -terms such that

$$M \Longrightarrow M_1 \Longrightarrow M_2 \Longrightarrow \cdots \Longrightarrow M_k \Longrightarrow N$$

By part **(b)**, we see that

$$M \xrightarrow{*}_{\beta} M_1 \xrightarrow{*}_{\beta} M_2 \xrightarrow{*}_{\beta} \cdots \xrightarrow{*}_{\beta} M_k \xrightarrow{*}_{\beta} N$$

which implies that $M \xrightarrow{*}_{\beta} N$. This completes the proof. \blacksquare

Lemma 0.1. $M \Longrightarrow M^*$ for all M .

Proof. We prove this by induction on the length of M . For the base case, suppose $M = x$ for a variable x . Clearly, we have $M^* = x^* = x = M$, and hence it follows that $M \Longrightarrow M^*$, i.e the base case is true.

Now suppose the statement is true for all terms of length atmost $n - 1$, where $n - 1 \in \mathbb{N}$. Let M be a term of length n . We consider a few cases.

- (1) Suppose $M = \lambda x.P$ for some P , where the length of P is atmost $n - 1$. Then, we see that

$$M^* = (\lambda x.P)^* = \lambda x.P^*$$

By the inductive hypothesis, we know that $P \Longrightarrow P^*$. So, it follows that

$$M = \lambda x.P \Longrightarrow \lambda x.P^* = M^*$$

and hence the claim is true in this case.

- (2) Suppose $M = PQ$ where P is not of the form $\lambda x.S$. Clearly, P and Q have length atmost $n - 1$. So, by the inductive hypothesis, we know that $P \Longrightarrow P^*$ and $Q \Longrightarrow Q^*$. Also,

$$M^* = (PQ)^* = P^*Q^*$$

So, it follows that

$$M = PQ \Longrightarrow P^*Q^* = M^*$$

and the claim is true in this case as well.

- (3) Finally, suppose M is of the form $(\lambda x.P)Q$. Clearly, the lengths of P and Q are atmost $n - 1$, and hence by the inductive hypothesis we see that $P \Longrightarrow P^*$ and $Q \Longrightarrow Q^*$. Also, note that $M^* = ((\lambda x.P)Q)^* = P^*[x := Q^*]$. So, we have

$$M = (\lambda x.P)Q \Longrightarrow P^*[x := Q^*] = M^*$$

So, by induction, the claim is true for all terms M , and this completes the proof. \blacksquare

(d) If $M \Longrightarrow N$ then $N \Longrightarrow M^*$.

Proof. We will prove this by induction on the size of M . For the base case, suppose M has size 1, i.e $M = x$ where x is a variable. Then, $N = x$, and hence $x \Longrightarrow x$. In this case, note that $M^* = x$. So, it follows that $N \Longrightarrow M^*$, and hence the base case is true.

Now, suppose the claim is true for all terms of size atmost $n - 1$ for some $n - 1 \in \mathbb{N}$. Let M be a term of size n such that $M \Longrightarrow N$. We handle a couple of cases.

- (1) Suppose the reduction $M \Longrightarrow N$ is of the form $M \Longrightarrow M$, i.e $N = M$. By **Lemma 0.1**, we know that $N = M \Longrightarrow M^*$.
- (2) Suppose $M = PQ$ where $P \Longrightarrow P'$ and $Q \Longrightarrow Q'$, and the reduction $M \Longrightarrow N$ is of the form $PQ \Longrightarrow P'Q'$. Since the lengths of both P and Q are atmost $n - 1$, from the induction hypothesis we get that $P' \rightarrow P^*$ and $Q' \rightarrow Q^*$. Now, we have two subcases here.
 - (a) If PQ is not a β -redux, then $M^* = P^*Q^*$. So $N = P'Q' \Longrightarrow P^*Q^* = M^*$, and hence we are done.
 - (b) Suppose PQ is a β -redux, say $P = \lambda x.S$, and hence $M^* = S^*[x := Q^*]$. Suppose the reduction $P \Longrightarrow P'$ was of the form $P = \lambda x.S \Longrightarrow \lambda x.S'$ where $S \Longrightarrow S'$. By induction hypothesis, we see that $S' \Longrightarrow S^*$, and since $Q' \Longrightarrow Q^*$, it follows that $N = (\lambda x.S')Q' \Longrightarrow S^*[x := Q^*] = M^*$.
- (3) Suppose $M = (\lambda x.Q)P$ and $N = Q'[x := P']$ where $Q \Longrightarrow Q'$ and $P \Longrightarrow P'$. Then $M^* = Q^*[x := P^*]$, and $N \Longrightarrow M^*$, because by the induction hypothesis we have $Q' \Longrightarrow Q^*$ and $P' \Longrightarrow P^*$.

So, by induction, the claim is true for all terms M of any size. This completes the proof. ■

(e) If $M \Longrightarrow P$ and $M \Longrightarrow Q$ then there exists N such that $P \Longrightarrow N$ and $Q \Longrightarrow N$.

Proof. This easily follows from part (d). Suppose $M \Longrightarrow P$ and $M \Longrightarrow Q$. Invoking part (d), we see that $P \Longrightarrow M^*$ and $Q \Longrightarrow M^*$. Setting $N = M^*$, this proves the claim. ■

2. Are the following expressions typable? If so, what are the most general types? If not, explain why.

(a) $\lambda f g x. f(gx)$

Solution. Yes, this term is typable. Let us derive the most general type for this. We begin with the following.

$$\begin{aligned} \tau_x &= p_x, & \tau_g &= p_g, & \tau_f &= p_f \\ E_x &= \phi, & E_g &= \phi, & E_f &= \phi \end{aligned}$$

From these, we get

$$\begin{aligned} \tau_{gx} &= a, & \tau_f &= p_f \\ E_{gx} &= \{p_g = p_x \rightarrow a\}, & E_f &= \phi \end{aligned}$$

Further, we get

$$\begin{aligned} \tau_{f(gx)} &= b \\ E_{f(gx)} &= \{p_g = p_x \rightarrow a, p_f = a \rightarrow b\} \end{aligned}$$

Going ahead, we have the following.

$$\begin{aligned}\tau_{\lambda x.f(gx)} &= c \rightarrow \tau_{f(gx)}[p_x := c] = c \rightarrow b \\ E_{\lambda x.f(gx)} &= E_{f(gx)}[p_x := c] = \{p_g = c \rightarrow a, p_f = a \rightarrow b\}\end{aligned}$$

Further, we have

$$\begin{aligned}\tau_{\lambda gx.f(gx)} &= d \rightarrow \tau_{\lambda x.f(gx)}[p_g := d] = d \rightarrow c \rightarrow b \\ E_{\lambda gx.f(gx)} &= E_{\lambda x.f(gx)}[p_g := d] = \{d = c \rightarrow a, p_f = a \rightarrow b\}\end{aligned}$$

Finally, we have

$$\begin{aligned}\tau_{\lambda fgx.f(gx)} &= e \rightarrow \tau_{\lambda gx.f(gx)}[p_f := e] = e \rightarrow d \rightarrow c \rightarrow b \\ E_{\lambda fgx.f(gx)} &= E_{\lambda gx.f(gx)}[p_f := e] = \{d = c \rightarrow a, e = a \rightarrow b\}\end{aligned}$$

So, it follows that the most general type of $\lambda fgx.f(gx)$ is

$$\tau_{\lambda fgx.f(gx)} = (a \rightarrow b) \rightarrow (c \rightarrow a) \rightarrow c \rightarrow b$$

and so we have found the required type. ■

(b) $\lambda xy.yx$

Solution. Yes, this term is also typable. Let us derive the most general type for this. We begin with the following.

$$\begin{aligned}\tau_x &= p_x, & \tau_y &= p_y \\ E_x &= \phi, & E_y &= \phi\end{aligned}$$

From this, we get the following.

$$\begin{aligned}\tau_{yx} &= a \\ E_{yx} &= \{p_y = p_x \rightarrow a\}\end{aligned}$$

From here, we can obtain the following.

$$\begin{aligned}\tau_{\lambda y.yx} &= b \rightarrow \tau_{yx}[p_y := b] = b \rightarrow a \\ E_{\lambda y.yx} &= E_{yx}[p_y := b] = \{b = p_x \rightarrow a\}\end{aligned}$$

Finally, we get

$$\begin{aligned}\tau_{\lambda xy.yx} &= c \rightarrow \tau_{\lambda y.yx}[p_x := c] = c \rightarrow b \rightarrow a \\ E_{\lambda xy.yx} &= E_{\lambda y.yx}[p_x := c] = \{b = c \rightarrow a\}\end{aligned}$$

So, it follows that the most general type of $\lambda xy.yx$ is

$$\tau_{\lambda xy.yx} = c \rightarrow (c \rightarrow a) \rightarrow a$$

and so we have found the required type. ■

(c) $\lambda fgx.g(fx)$

Solution. Yes, this term is typable. Let us derive the most general type for this. We begin with the following.

$$\begin{aligned}\tau_x &= p_x, & \tau_g &= p_g, & \tau_f &= p_f \\ E_x &= \phi, & E_g &= \phi, & E_f &= \phi\end{aligned}$$

From these, we get

$$\begin{aligned}\tau_{fx} &= a \\ E_{fx} &= \{p_f = p_x \rightarrow a\}\end{aligned}$$

Further, we get

$$\begin{aligned}\tau_{g(fx)} &= b \\ E_{g(fx)} &= \{p_f = p_x \rightarrow a, p_g = a \rightarrow b\}\end{aligned}$$

Going ahead, we have the following.

$$\begin{aligned}\tau_{\lambda x.g(fx)} &= c \rightarrow \tau_{g(fx)}[p_x := c] = c \rightarrow b \\ E_{\lambda x.g(fx)} &= E_{g(fx)}[p_x := c] = \{p_f = c \rightarrow a, p_g = a \rightarrow b\}\end{aligned}$$

Further, we have

$$\begin{aligned}\tau_{\lambda gx.g(fx)} &= d \rightarrow \tau_{\lambda x.g(fx)}[p_g := d] = d \rightarrow c \rightarrow b \\ E_{\lambda gx.g(fx)} &= E_{\lambda x.g(fx)}[p_g := d] = \{p_f = c \rightarrow a, d = a \rightarrow b\}\end{aligned}$$

Finally, we have

$$\begin{aligned}\tau_{\lambda fgx.g(fx)} &= e \rightarrow \tau_{\lambda gx.g(fx)}[p_f := e] = e \rightarrow d \rightarrow c \rightarrow b \\ E_{\lambda fgx.g(fx)} &= E_{\lambda gx.g(fx)}[p_f := e] = \{e = c \rightarrow a, d = a \rightarrow b\}\end{aligned}$$

So, it follows that the most general type of $\lambda fgx.g(fx)$ is

$$\tau_{\lambda fgx.g(fx)} = (c \rightarrow a) \rightarrow (a \rightarrow b) \rightarrow c \rightarrow b$$

and so we have found the required type. ■

3. Recall the following standard encodings: $f^0x = x$, $f^{n+1}x = f(f^n x)$, $[n] = (\lambda fx.f^n x)$, **true** = $(\lambda xy.x)$, **false** = $(\lambda xy.y)$, **pair** = $(\lambda xyw.wxy)$, **fst** = $(\lambda p.p \text{ true})$, **snd** = $(\lambda p.p \text{ false})$, **ite** = $(\lambda bxy.bxy)$ and **iszero** = $(\lambda x.(x(\lambda z.\text{false}))\text{true})$

Derive the most general types of each of the above expressions. If you feel that any of them is untypable, give a justification.

Solution. We will find the types individually below.

Type of $[n]$. If $n = 0$, then

$$[0] = \lambda fx.x$$

We will now derive the most general type of this using the following steps.

- (1) $\tau_x = p_x, \tau_f = p_f$ and $E_f = \phi, E_x = \phi$.
- (2) $\tau_{\lambda x.x} = a \rightarrow \tau_x[p_x := a] = a \rightarrow a$ and $E_{\lambda x.x} = E_x[p_x := a] = \phi$.
- (3) $\tau_{\lambda fx.x} = b \rightarrow \tau_{\lambda x.x}[p_f := b] = b \rightarrow a \rightarrow a$ and $E_{\lambda fx.x} = E_{\lambda x.x}[p_f := b] = \phi$.

So, we see that the type of 0 is $b \rightarrow a \rightarrow a$.

Next, suppose $n \geq 1$. So,

$$[n] = \lambda fx.f^n x$$

Consider the following steps.

- (1) $\tau_x = p_x, \tau_f = p_f$ and $E_f = \phi, E_x = \phi$.
- (2) $\tau_{fx} = a_1$ and $E_{\lambda fx} = \{p_f = p_x \rightarrow a_1\}$.
- (3) $\tau_{f^2x} = a_2$ and $E_{f^2x} = \{p_f = p_x \rightarrow a_1, p_f = a_1 \rightarrow a_2\}$.
- (4) Continuing this way n times, we will obtain: $\tau_{f^n x} = a_n$ and $E_{f^n x} = \{p_f = p_x \rightarrow a_1, p_f = a_1 \rightarrow a_2, p_f = a_2 \rightarrow a_3, \dots, p_f = a_{n-1} \rightarrow a_n\}$
- (5) $\tau_{\lambda x.f^n x} = a \rightarrow \tau_{f^n x}[p_x := a] = a \rightarrow a_n$ and $E_{\lambda x.f^n x} = E_{f^n x}[p_x := a] = \{p_f = a \rightarrow a_1, p_f = a_1 \rightarrow a_2, \dots, p_f = a_{n-1} \rightarrow a_n\}$.

- (6) $\tau_{\lambda f x. f^n x} = b \rightarrow \tau_{\lambda x. f^n x}[p_f := b] = b \rightarrow a \rightarrow a_n$ and $E_{\lambda f x. f^n x} = E_{\lambda x. f^n x}[p_f := b] = \{b = a \rightarrow a_1, b = a_1 \rightarrow a_2, \dots, b = a_{n-1} \rightarrow a_n\}$.

The only solution to this system is $a = a_1 = a_2 = \dots a_n$. So, it follows that the type of $[n]$ in this case is $(a \rightarrow a) \rightarrow a \rightarrow a$.

Type of true. Consider the following steps.

- (1) $\tau_x = p_x, \tau_y = p_y$ and $E_x = \phi, E_y = \phi$.
- (2) $\tau_{\lambda y. x} = a \rightarrow p_x$ and $E_{\lambda y. x} = \phi$.
- (3) $\tau_{\lambda x y. x} = b \rightarrow a \rightarrow b$ and $E_{\lambda x y. x} = \phi$.

So, the type of **true** is $b \rightarrow a \rightarrow b$.

Type of false. This derivation is very similar to the type derivation of **true**, and I won't repeat it. The type of **false** turns out to be $b \rightarrow a \rightarrow a$.

Type of pair. Consider the following steps.

- (1) $\tau_w = p_w, \tau_y = p_y, \tau_x = p_x$ and $E_w = E_y = E_x = \phi$.
- (2) $\tau_{wx} = a$ and $E_{wx} = \{p_w = p_x \rightarrow a\}$.
- (3) $\tau_{wxy} = b$ and $E_{wxy} = \{p_w = p_x \rightarrow a, a = p_y \rightarrow b\}$.
- (4) $\tau_{\lambda w. wxy} = c \rightarrow b$ and $E_{\lambda w. wxy} = \{c = p_x \rightarrow a, a = p_y \rightarrow b\}$.
- (5) $\tau_{\lambda y w. wxy} = d \rightarrow c \rightarrow b$ and $E_{\lambda y w. wxy} = \{c = p_x \rightarrow a, a = d \rightarrow b\}$.
- (6) $\tau_{\lambda x y w. wxy} = e \rightarrow d \rightarrow c \rightarrow b$ and $E_{\lambda x y w. wxy} = \{c = e \rightarrow a, a = d \rightarrow b\}$.

So, the type of **pair** is $e \rightarrow d \rightarrow (e \rightarrow (d \rightarrow b)) \rightarrow b$.

Type of fst. Consider the following steps. We will assume that the type of **true** (which we derived above) is $b \rightarrow a \rightarrow b$.

- (1) $\tau_p = p_p$ and $E_p = \phi$.
- (2) $\tau_p \text{ true} = c$ and $E_p \text{ true} = \{p_p = \tau_{\text{true}} \rightarrow c = (b \rightarrow a \rightarrow b) \rightarrow c\}$.
- (3) $\tau_{\lambda p. p \text{ true}} = d \rightarrow c$ and $E_{\lambda p. p \text{ true}} = \{d = (b \rightarrow a \rightarrow b) \rightarrow c\}$

With these steps, the type of **fst** is $(b \rightarrow a \rightarrow b) \rightarrow c \rightarrow c$.

Type of snd. This is very similar to the case of **fst**. If we follow the steps of type derivation, we will get that the type of **snd** is $(b \rightarrow a \rightarrow a) \rightarrow c \rightarrow c$.

Type of ite. Consider the following steps.

- (1) $\tau_b = p_b, \tau_y = p_y, \tau_x = p_x$ and $E_b = E_y = E_x = \phi$.
- (2) $\tau_{bx} = a$ and $E_{bx} = \{p_b = p_x \rightarrow a\}$.
- (3) $\tau_{bxy} = b$ and $E_{bxy} = \{p_b = p_x \rightarrow a, a = p_y \rightarrow b\}$.
- (4) $\tau_{\lambda y. bxy} = c \rightarrow b$ and $E_{\lambda y. bxy} = \{p_b = p_x \rightarrow a, a = c \rightarrow b\}$.
- (5) $\tau_{\lambda x y. bxy} = d \rightarrow c \rightarrow b$ and $E_{\lambda x y. bxy} = \{p_b = d \rightarrow a, a = c \rightarrow b\}$.
- (6) $\tau_{\lambda b x y. bxy} = e \rightarrow d \rightarrow c \rightarrow b$ and $E_{\lambda b x y. bxy} = \{e = d \rightarrow a, a = c \rightarrow b\}$.

It follows that the type of **ite** is $(d \rightarrow (c \rightarrow b)) \rightarrow d \rightarrow c \rightarrow b$.

Type of iszero. We assume that the types of **true** and **false** are $a \rightarrow b \rightarrow a$ and $c \rightarrow d \rightarrow d$ respectively. Consider the following steps.

- (1) $\tau_{\text{false}} = c \rightarrow d \rightarrow d$.
- (2) $\tau_{\lambda z. \text{false}} = e \rightarrow (c \rightarrow d \rightarrow d)$ and $E_{\lambda z. \text{false}} = \phi$.
- (3) $\tau_x = p_x$ and $E_x = \phi$.
- (4) $\tau_{x(\lambda z. \text{false})} = f$ and $E_{x(\lambda z. \text{false})} = \{p_x = (e \rightarrow (c \rightarrow d \rightarrow d)) \rightarrow f\}$.
- (5) $\tau_{(x(\lambda z. \text{false})) \text{ true}} = g$ and $E_{(x(\lambda z. \text{false})) \text{ true}} = \{p_x = (e \rightarrow (c \rightarrow d \rightarrow d)) \rightarrow f, f = (a \rightarrow b \rightarrow a) \rightarrow g\}$.

$$(6) \tau_{\lambda x.(x(\lambda z.\mathbf{false}))\mathbf{true}} = h \rightarrow g \text{ and } E_{\lambda x.(x(\lambda z.\mathbf{false}))\mathbf{true}} = \{h = (e \rightarrow (c \rightarrow d \rightarrow d)) \rightarrow f, f = (a \rightarrow b \rightarrow a) \rightarrow g\}.$$

So, it follows that the type of **iszero** is

$$(e \rightarrow (c \rightarrow d \rightarrow d)) \rightarrow ((a \rightarrow b \rightarrow a) \rightarrow g) \rightarrow g$$

■
